

Greenish Warbler Genomic Analysis

Darren Irwin

2023-09-10

This page contains notes and code describing the data analysis for a manuscript on Greenish Warbler genomics. I've been working with the data for several years, and the R and then Julia code has been in development for a while. This is a Quarto notebook, which can run and display the results of Julia (or other) code blocks, along with text narration, and output in html, pdf, Word, etc.

The Julia code here is loosely based on R code written for Greenish Warbler analysis (Irwin et al. 2016), and then the North American warbler analyses (Irwin et al. 2019), and then my (unpublished) 2019 Greenish Warbler analysis. Most recently, this was adapted from the scripts called GW2022_R_analysis_script.R and IrwinLabGenomicsAnalysisScript.jl but has had a lot of optimizations since then. The SNP data here are a result of GBS reads mapped to our new 2022 Biozeron genome assembly for a greenish warbler from southern China.

Load packages

If running this for the first time, you will need to load packages used in the script, so run what is in this section below. It will take some time to install and precompile the packages:

```
import Pkg; Pkg.add("CSV") # took less than a minute
Pkg.add("DataFrames") # took about a minute
Pkg.add("Plots") # seems to install and working more simply than Makie (but less powerful)
Pkg.add("Haversine") # for great circle (Haversine) distances
Pkg.add("Distributions") # this seemed to fix a problem installing GLMakie
Pkg.add("MultivariateStats")
Pkg.add("StatsBase")
Pkg.add("Impute")
Pkg.add("JLD2")
Pkg.add("CairoMakie")
Pkg.add("PrettyTables") # for printing nice tables to REPL
```

Now actually load those packages into the Julia session:

```
using CSV # for reading in delimited files
using DataFrames # for storing data as type DataFrame
using Haversine # for calculating Great Circle (haversine) distances between sites
using MultivariateStats # for Principal Coordinates Analysis (multidimensional scaling)
using DelimitedFiles # for reading delimited files (the genotypic data)
using Impute # for imputing missing genotypes
using JLD2 # for saving data
using CairoMakie # for plots
CairoMakie.activate!() # this makes CairoMakie the main package for figures (in case another already
```

Load my custom package SNPlots:

```
include("SNPlots.jl") # load file containing custom-built functions
using .SNPlots # actually make SNPlots module available with SNPlots.functionName(),
# or if functions are exported from SNPlots then they are available.
```

Test Julia:

```
x = 1; y = 2; z = x+y
println("z = ", z)
```

z = 3

(If Quarto is calling Julia properly, you will see `z = 3` as the output of the code block above.)

Choose working directory:

```
cd("/Users/darrenirwin/Dropbox/Darren's current work/")
```

OK, let's load the genomic data!

```
# choose path and filename for the 012NA files
baseName = "GW_genomics_2022_with_new_genome/GW2022_GBS_012NA_files/GW2022_all4plates.genotypes.SNPs."
filenameTextMiddle = ".max2allele_noindel.vcf.maxmiss"
# indicate percent threshold for missing genotypes for each SNP--
# this was set by earlier filtering, and is just a record-keeper for the filenames:
missingGenotypeThreshold = 60
filenameTextEnd = ".MQ20.lowHet.tab"
tagName = ".Aug2023." # choose a tag name for this analysis
```

```

# indicate name of metadata file, a text file with these column headings:
# ID      location      group      Fst_group      plot_order
metadataFile = "GW_genomics_2022_with_new_genome/GW_all4plates.Fst_groups.txt"
# load metadata
metadata = DataFrame(CSV.File(metadataFile)) # the CSV.File function interprets the correct delimiters
num_metadata_cols = ncol(metadata)
num_individuals = nrow(metadata)
# read in individual names for this dataset
individuals_file_name = string(baseName, filenameTextMiddle, missingGenotypeThreshold, filenameTextEnd)
ind = DataFrame(CSV.File(individuals_file_name; header=["ind"], types=[String]))
indNum = size(ind, 1) # number of individuals
if num_individuals != indNum
    println("WARNING: number of rows in metadata file different than number of individuals in .indv file")
end
# read in position data for this dataset
position_file_name = string(baseName, filenameTextMiddle, missingGenotypeThreshold, filenameTextEnd)
pos_whole_genome = DataFrame(CSV.File(position_file_name; header=["chrom", "position"], types=[String, Int64]))
# read in genotype data
column_names = ["null"; string("c.", pos_whole_genome.chrom, ".", pos_whole_genome.position)]
genotype_file_name = string(baseName, filenameTextMiddle, missingGenotypeThreshold, filenameTextEnd)
@time if 1 <= indNum <= 127
    geno = readlm(genotype_file_name, '\t', Int8, '\n'); # this has been sped up dramatically, by factor of 10
elseif 128 <= indNum <= 32767
    geno = readlm(genotype_file_name, '\t', Int16, '\n'); # this needed for first column, which is a count from zero
else
    print("Error: Number of individuals in .indv appears outside of range from 1 to 32767")
end
loci_count = size(geno, 2) - 1 # because the first column is not a SNP (just a count from zero)
print(string("Read in genotypic data at ", loci_count, " loci for ", indNum, " individuals. \n"))

```

50.430901 seconds (3.61 M allocations: 9.585 GiB, 0.17% gc time, 0.64% compilation time)
Read in genotypic data at 2431709 loci for 310 individuals.

Check that individuals are same in genotype data and metadata

```

ind_with_metadata = hcat(ind, metadata)
print(ind_with_metadata)
print("\n") # prints a line break
if isequal(ind_with_metadata.ind, ind_with_metadata.ID)
    println("GOOD NEWS: names of individuals in metadata file and genotype ind file match perfectly.")
end

```

```
else
```

```
  println("WARNING: names of individuals in metadata file and genotype ind file do not completely match")
```

```
end
```

GOOD NEWS: names of individuals in metadata file and genotype ind file match perfectly.

Filtering

Filter specific individuals

If there are certain individuals that we want to filter out prior to any additional analysis, we can do so here by setting filter to true and specifying the individual row numbers in filter_out_inds:

```
filter = false
filter_out_inds = [] # if filtering out individuals, specify their row number here, e.g. "[20, 103]"
if filter
  # Specify individuals to filter out:
  ind_with_metadata_indFiltered = ind_with_metadata[Not(filter_out_inds), :]
  geno_indFiltered = geno[Not(filter_out_inds), :]
  println("Specific individuals filtered out as requested")
}
```

```

else
  ind_with_metadata_indFiltered = ind_with_metadata
  geno_indFiltered = geno
  println("No specific individuals requested to be filtered out")
end

```

No specific individuals requested to be filtered out

Filter individuals based on missing genotypes

Here we determine number of missing SNPs per bird (40% for this round), and filter out those with more than a certain percent of missing SNPs:

```

SNPmissing_percent_allowed_per_ind = 40 # this is the percentage threshold
threshold_missing = loci_count * SNPmissing_percent_allowed_per_ind/100
numMissings = sum(geno == -1, dims=2)
selection = vec(numMissings <= threshold_missing) # the vec command converts to BitVector rather than Bool
geno_indFiltered = geno_indFiltered[selection, :]
println("Filtering out these individuals based on too many missing genotypes: ", ind_with_metadata_indFiltered[selection, :])
ind_with_metadata_indFiltered = ind_with_metadata_indFiltered[selection, :];

```

Filtering out these individuals based on too many missing genotypes: ["GW_Armando_plate1_JG08G02", "GW_Armando_plate1_JG08G02"]

Filter SNPs with too many missing genotypes:

```

# (remember that first column is arbitrary row number in input file)
missing_genotypes_per_SNP = sum(geno_indFiltered == -1, dims=1)
missing_genotypes_percent_allowed_per_site = 5 # this is the percentage threshold
threshold_genotypes_missing = size(geno_indFiltered)[1] * missing_genotypes_percent_allowed_per_site
selection = vec(missing_genotypes_per_SNP <= threshold_genotypes_missing)
geno_ind_SNP_filtered = geno_indFiltered[:, selection]
pos_SNP_filtered = pos_whole_genome[selection[Not(1)],:] # the Not(1) is needed because first column is row number
println("Started with ", size(geno_indFiltered, 2)-1, " SNPs. After filtering SNPs for no more than 5% missing genotypes, 1003400 SNPs remain.")

```

Started with 2431709 SNPs. After filtering SNPs for no more than 5% missing genotypes, 1003400 SNPs remain.

2nd round of filtering individuals

I added this in August 2023, to improve accuracy of imputation-based PCA, because I noticed outliers tended to have more missing data. Now I only allow up to 10% missing SNPs per individual.

```
SNPmissing_percent_allowed_per_ind_round2 = 10 # this is the percentage threshold
threshold_missing = (size(geno_ind_SNP_filtered, 2) - 1) * SNPmissing_percent_allowed_per_ind_round2
numMissings = sum(geno_ind_SNP_filtered .== -1, dims=2)
selection = vec(numMissings .<= threshold_missing) # the vec command converts to BitVector rather than Bool
geno_ind_SNP_ind_filtered = geno_ind_SNP_filtered[selection, :]
# print filtered out individuals:
ind_with_metadata_indFiltered.ind[selection.==false]
println("Filtering out these individuals based on too many missing genotypes: ", ind_with_metadata_indFiltered.ind[selection.==false])
# filtered out: ["GW_Armando_plate1_TTGW74", "GW_Armando_plate2_TTGW54", "GW_Lane5_AA8", "GW_Lane5_Y"]
ind_with_metadata_indFiltered = ind_with_metadata_indFiltered[selection, :]
println("This leaves ", size(geno_ind_SNP_ind_filtered, 1), " individuals and ", size(geno_ind_SNP_ind_filtered, 2), " loci")
```

Filtering out these individuals based on too many missing genotypes: ["GW_Armando_plate1_TTGW74", "GW_Armando_plate2_TTGW54", "GW_Lane5_AA8", "GW_Lane5_Y"]
This leaves 267 individuals and 1003400 loci, with no individuals missing more than 10% of genotypes and no loci missing more than 10% of individuals

Estimate relationships of individuals using PCA

Our goal is to produce plots showing individuals in genotype space, using Principal Components Analysis. First we need to do a couple changes to our data matrix:

For missing genotypes, change our code of -1 to missing:

```
genos_with_missing = Matrix{Union{Missing, Int32}}(geno_ind_SNP_ind_filtered)
genos_with_missing[genos_with_missing .== -1] .= missing;
```

Remove the first column of the genotype matrix (which was an initial row number):

```
genosOnly = genos_with_missing[:,Not(1)]
```

267×1003400 Matrix{Union{Missing, Int32}}:

```
0 0 0 1 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 ... 0 0 0 0 0 0 0 0 0 0 0 0
```

| | | | | | | | | | | | | | | | | | | | | | | | |

Impute and save genotypes for each scaffold

PCA requires imputation of missing genotypes. I did imputation for each scaffold above a certain size threshold. Those scaffolds (many of which correspond to whole chromosomes) are listed here:

```
chromosomes_to_process = ["gw2",
                          "gw1",
                          "gw3",
                          "gwZ",
                          "gw1A",
                          "gw4",
                          "gw5",
                          "gw7",
                          "gw6",
                          "gw8",
                          "gw9",
                          "gw11",
                          "gw12",
                          "gw10",
                          "gw13",
```

```

"gw14",
"gw18",
"gw20",
"gw15",
"gw1B",
"gws100",
"gw17",
"gw19",
"gws101",
"gw4A",
"gw21",
"gw26",
"gws102",
"gw23",
"gw25",
"gws103",
"gw22",
"gws104",
"gw28",
"gw27",
"gw24",
"gws105",
"gws106",
"gws107",
"gws108",
"gws109",
"gws110",
"gws112"];

```

Imputation can take several minutes per scaffold, so I ran this imputation step separately from this Quarto notebook (otherwise render would take long) and saved the genotype data for each scaffold for loading in the next step. This is the code I used for imputing:

```

for i in eachindex(chromosomes_to_process)
    chrom = chromosomes_to_process[i]
    regionText = string("chr", chrom)
    loci_selection = (pos_SNP_filtered.chrom .== chrom)
    pos_SNP_filtered_region = pos_SNP_filtered[loci_selection,:]
    genosOnly_region_for_imputing = Matrix{Union{Missing, Float32}}(genosOnly[:,loci_selection])
    @time imputed_genos = Impute.svd(genosOnly_region_for_imputing)
    filename = string(baseName, tagName, regionText, ".imputedMissing.jld2")

```

```

        jldsave(filename; imputed_genos, ind_with_metadata_indFiltered, pos_SNP_filtered_region)
        println(string("Chromosome ", chrom, ": Saved real and imputed genotypes for ", size(pos_SNP_filtered_region, 1)))
    end
end

```

Now we can cycle through a set of chromosomes and plot a PCA for each. We need to first specify some groups to include in the plot, and their colors:

```

groups_to_plot_PCA = ["vir", "vir_misID", "vir_S", "nit", "lud_PK", "lud_KS", "lud_central", "lud_Sath"]
group_colors_PCA = ["blue", "blue", "turquoise1", "grey", "seagreen4", "seagreen3", "seagreen2", "olivedrab"]

```

Now we'll actually do the PCA and make the plot for each scaffold:

```

for i in eachindex(chromosomes_to_process)
    chrom = chromosomes_to_process[i]
    regionText = string("chr", chrom)
    filename = string(baseName, tagName, regionText, ".imputedMissing.jld2")
    imputed_genos = load(filename, "imputed_genos")
    ind_with_metadata_indFiltered = load(filename, "ind_with_metadata_indFiltered")
    pos_SNP_filtered_region = load(filename, "pos_SNP_filtered_region")
    println(string("Loaded ", filename))
    println(string(regionText, ": ", size(imputed_genos, 2), " SNPs from ", size(imputed_genos, 1), " individuals"))
    plotPCA(imputed_genos, ind_with_metadata_indFiltered,
            groups_to_plot_PCA, group_colors_PCA;
            sampleSet = "greenish warblers", regionText=regionText,
            flip1 = true, flip2 = false)
end

```

```

Whole-genome PCA

In addition to making PCA plots for each scaffold, we can do one for the whole genome. The imputing for the whole genome takes some time (almost 2 hours!), so I did this in advance and saved a file. This is incorporated into the code below—to actually do the imputing, set `do_imputing = true`. Otherwise this code will load the previously-imputed data.

(NOTE: this is using an older version of the data—sometime need to update by removing `tempTagName` and replacing with `tagName`)

```
genosOnly_for_imputing = Matrix{Union{Missing, Float32}}(genosOnly)
regionText = "wholeGenome"
tempTagName = ".June2023."
filename = string(baseName, tempTagName, regionText, ".imputedMissing.jld2")
# to do the imputing, do this by setting to true, but TAKES A LONG TIME:
do_imputing = false
if do_imputing
    @time imputed_genosOnly = Impute.svd(genosOnly_for_imputing)
    # took almost 2 hours!
    jldsave(filename; imputed_genosOnly, ind_with_metadata_indFiltered, pos_SNP_filtered)
```

```

    imputed_genosOnly_wholeGenome = imputed_genosOnly
    ind_with_metadata_indFiltered_wholeGenome = ind_with_metadata_indFiltered
    pos_SNP_filtered_wholeGenome = pos_SNP_filtered
    print("Saved matrix of real and imputed genotypes for filtered individuals. \n")
else # load the already saved imputing
    imputed_genosOnly_wholeGenome = load(filename, "imputed_genosOnly")
    ind_with_metadata_indFiltered_wholeGenome = load(filename, "ind_with_metadata_indFiltered")
    pos_SNP_filtered_wholeGenome = load(filename, "pos_SNP_filtered")
    println(string("Loaded ", filename))
    println(string(regionText, ": ", size(imputed_genosOnly_wholeGenome, 2), " SNPs from ", size(impu
end

```

Loaded GW_genomics_2022_with_new_genome/GW2022_GBS_012NA_files/GW2022_all4plates.genotypes.SNPs_only.wh
wholeGenome: 1003400 SNPs from 271 individuals

Now make the whole-genome PCA:

```

plotPCA(imputed_genosOnly_wholeGenome,
        ind_with_metadata_indFiltered_wholeGenome,
        groups_to_plot_PCA, group_colors_PCA;
        sampleSet = "greenish warblers", regionText=regionText,
        flip1 = true, flip2 = true)

```

CairoMakie.Screen{IMAGE}

Genotype-by-individual plots

Now, show individual genotypes for subsets of the dataset. Can choose individuals and genomic regions to plot, along with an Fst cutoff (only show SNPs with greater Fst than the cutoff).

```
set = "67_inds_around_ring" # "east_side_of_ring" # "67_inds_around_ring" # "west_side_of_ring"

if set == "67_inds_around_ring"
    groups = ["vir", "troch_LN", "plumb"] # for purpose of calculating pairwise Fst and Fst_group (to c
    plotGroups = ["vir", "vir_S", "lud_PK", "lud_KS", "lud_central", "troch_LN", "troch_EM", "obs", "plumb_L
    plotGroupColors = ["blue", "turquoise1", "seagreen4", "seagreen3", "seagreen2", "yellow", "gold", "orange"]
    numIndsToPlot = [10, 5, 6, 2, 7, 15, 15, 15, 15, 15] # maximum number of individuals to plot from

end

```

0.2

Calculate allele freqs and sample sizes (use column Fst_group)

```

freqs, sampleSizes = getFreqsAndSampleSizes(genosOnly, ind_with_metadata_indFiltered.Fst_group, group)
println("Calculated population allele frequencies and sample sizes")

```

Calculated population allele frequencies and sample sizes

calculate Fst

```

Fst, FstNumerator, FstDenominator, pairwiseNamesFst = getFst(freqs, sampleSizes, groups; among=true)
println("Calculated Fst values")

```

Calculated Fst values

limit the individuals to include in plot

```

genosOnly_included, ind_with_metadata_included = limitIndsToPlot(plotGroups, numIndsToPlot, genosOnly)

```

choose the scaffold and region to show

```

chr = "gw26"
regionInfo = chooseChrRegion(pos_SNP_filtered, chr; positionMin=1, positionMax=NaN) # this gets the region

```

("gw26", 1, 8896755, "gw26_whole")

NOTE FOR LATER: SHOULD REALLY GET CHROMOSOME LENGTH FOR position-Max

Now actually make the plot

```
plotInfo = plotGenotypeByIndividual(groupsToCompare, Fst_cutoff, missingFractionAllowed,
    regionInfo, pos_SNP_filtered, Fst, pairwiseNamesFst,
    genosOnly_included, ind_with_metadata_included, freqs, plotGroups, plotGroupColors);
# plotInfo contains a tuple with: (f, plottedGenotype, locations, plottedMetadata)
```

gw26_whole: genotypes Fst>0.7 loci between vir_plumb
